

TRF Decision Tree Anatomy

Fixed-depth traversal: $d = 4$ levels (one per attribute); bound $d \leq 7$ in the general model

Per-level role (Ordering 4)

L1 Root: split on protocol (3 atomic classes)

L2 Disjoint `dst_ip` ranges (Corollary 1.B, Theorem 2)

L3 `dst_port` refinement in the protocol domain (Def. 1.bis)

L4 `src_ip` filter; leaf = action. Every packet: one leaf

Per-packet work is $O(d \cdot c)$: $d = 4$ levels; $c =$ child-selection cost at a node, which grows with fan-out (Section 7.3).
